

# **Discussion on the Suitability of SWAT Model Applied to Hydrological Simulation of Paddy Field in Taiwan**

Li-Chi Chiang  
National Taiwan University  
Department of Bioenvironmental Systems  
Engineering

# Content

- **Introduction**

- Irrigation Methods
- Paddy Field Models
- Research Objectives

- **Study Area**

- **Methodology**

- SWAT Model
- Data Preparation
- Model Calibration and Validation
- Scenario Settings: plowsole depths and irrigation operations

- **Results and Discussion**

- Reclassification of Paddy Field
- Simulation results
  - Plowsole depths
  - Traditional irrigation vs. auto-irrigation

- **Conclusion**

# Introduction (1/4)

## Hydrology of paddy fields in Taiwan

- The climate and geographical conditions in Taiwan
- Agricultural management for irrigation and drainage operations

## Characteristics of rice

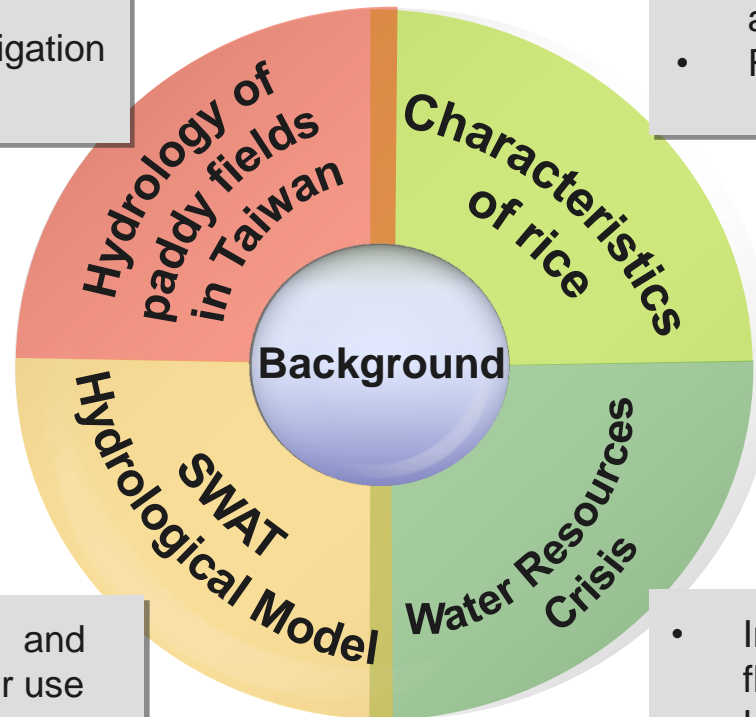

- Plentiful rainfall in Taiwan leads agricultural advantage
- Rice is the staple food in Taiwan

## Hydrological Model

- Simulation of water supply and demand for optimizing total water use
- Streamflow simulation at different temporal scales

## Water Resources Crisis

- Increasing and intensifying drought and flood
- Unstable irrigation water for paddy

# Introduction (2/4)

## • Irrigation Methods

### **Continuous irrigation**

- Interval irrigation
- Continuous irrigation with water drainage

### **Rotational irrigation**

- Standard rotational irrigation
- Precision rotational irrigation
- Large area rotational irrigation

### **Special rotational irrigation**

- Method of reduced water depth
- Method of extended interval
- Method of reduced irrigation area

Traditional Methods

# Introduction (3/4)

## • Paddy Field Models

- Kamruzzaman et al. (2020) used APEX-Paddy to assess the impact of BMPs on paddy fields due to climate change.
  - Jeon et al. (2007) compared changes in water quality of paddy fields using HSPF-Paddy of different scales.
- Yan et al. (2016) analyzed the effectiveness of water resources management with improved WALRUS-Paddy.
  - Janssen et al. (2010) developed the PADDY-FLUX model to assess the impact of water resources management on infiltration.
- Kang et al. (2016) evaluated the simulation results of reservoir water level with COMFARM.

Advantage of SWAT model:

The SWAT model can be simulated and verified by adjusting relevant parameters. Compared with other hydrological models, it has advantageous features such as **continuously simulating** watershed at a **fine spatial scales over a long-term period**.

# Introduction (4/4)

- Objectives

## Integration of paddy land use

- Development of the land use classification and integration method to reflect the actual irrigated area of paddy fields.

## Evaluate the applicability of simulation

- Examine the irrigation/drainage mechanism of paddy in the SWAT model, and analyze the HRU water balance of paddy fields to evaluate the applicability of SWAT model in paddy field simulation.

# Study Area (1/2)

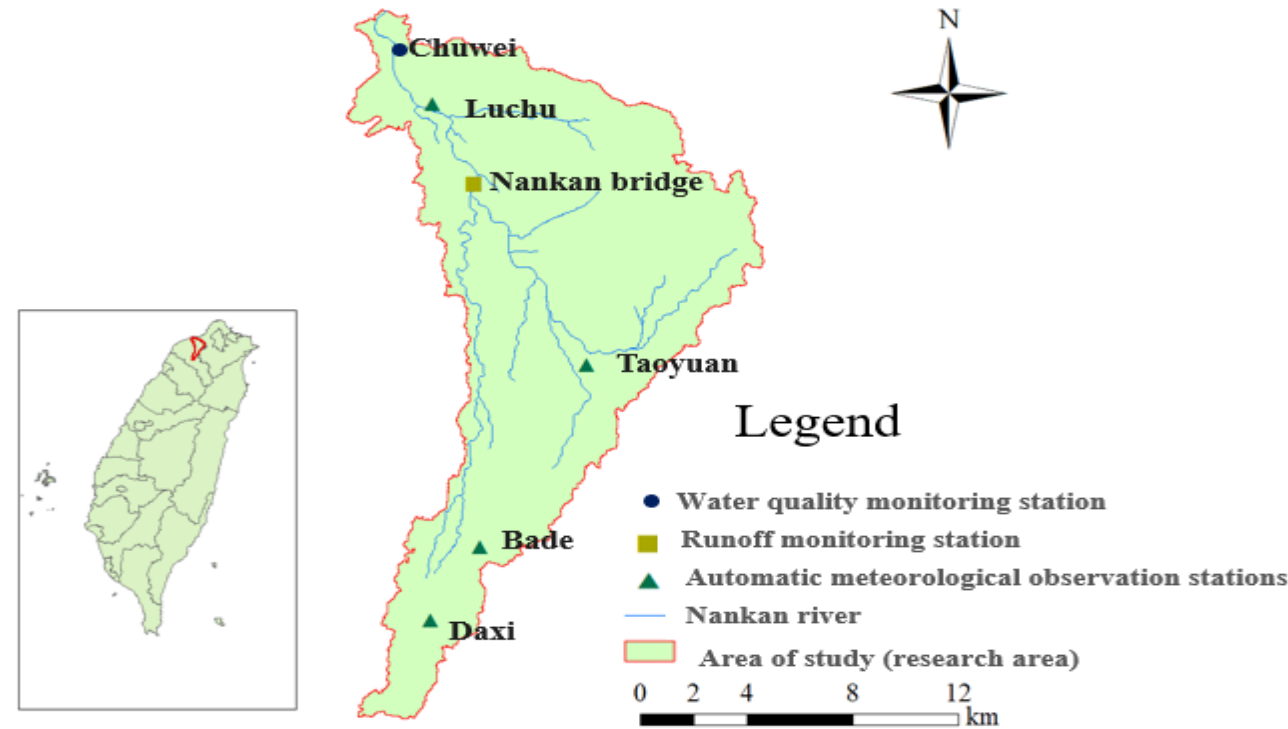

## • Nankan River Basin

- Originates from: Pingding plateau in Taoyuan
- Total length of Nankan river: 30.7 km
- Drainage area: 214.7 km<sup>2</sup>
- Average slope: 1/186

- Average RPI (1999 ~ 2014): 4.35
- Historical severe contamination: 7.3 at the Chuwei bridge monitoring station in September 2019

- Governed by: Taoyuan and Shimen Management Offices
- Irrigation supply: 40% ~ 44% from river, 56% ~ 60% from reservoir or/and ponds

Degree of Contamination	Uncontaminated/ Slightly contaminated	Mild contamination	Medium contamination	Severe contamination
RPI	< 2.0	2.0 - 3.0	3.1 - 6.0	> 6.0

# Study Area (2/2)

**0-15%:78.29%**  
**15-30%:11.00%**  
**Others: 10.71%**

**Woodland: 21.70%**  
**Residential area: 23.75%**  
**Paddy fields: 18.11%**  
**Others: 36.44%**

**Red soil: 47.40%**  
**Alluvial soil: 20.98%**  
**Yellow soil: 11.34%**  
**Others: 20.28%**

# Methodology (1/8)

- SWAT Model

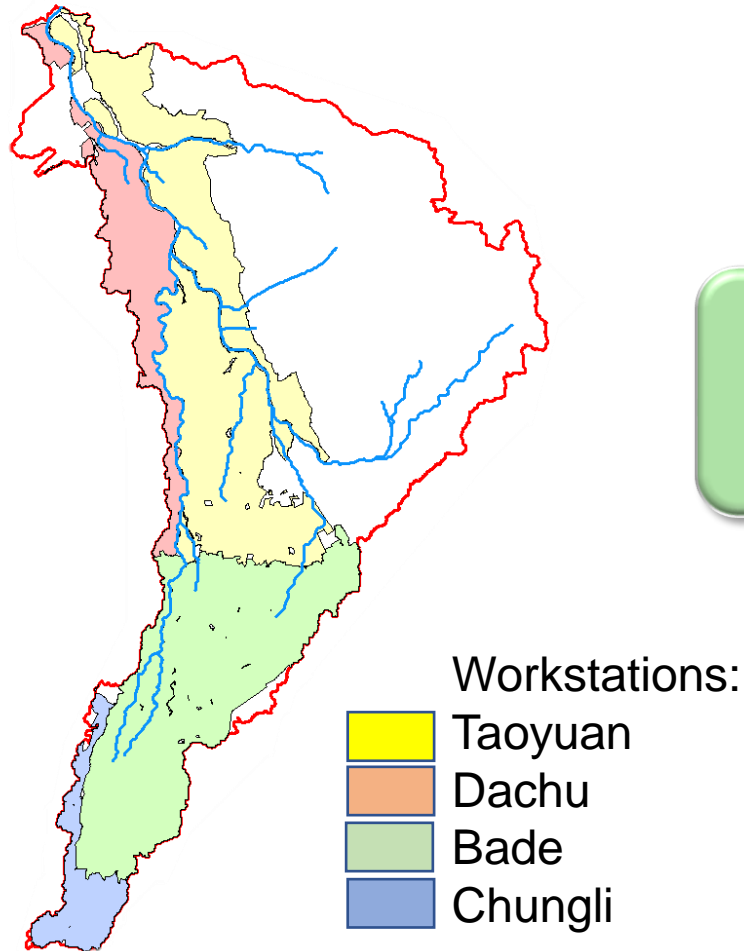

SWAT model can simulate hydrological and water quality features of river tributaries and the subbasins at various spatio-temporal scales.

SWAT subdivides the watershed into smaller subbasins according to the distribution of the tributaries of the river and the monitoring points, then further classifies the smallest calculation units: **Hydrological Response Unit (HRU)**, which is a unique combination of land use, soil type and land slope in each subbasin area.

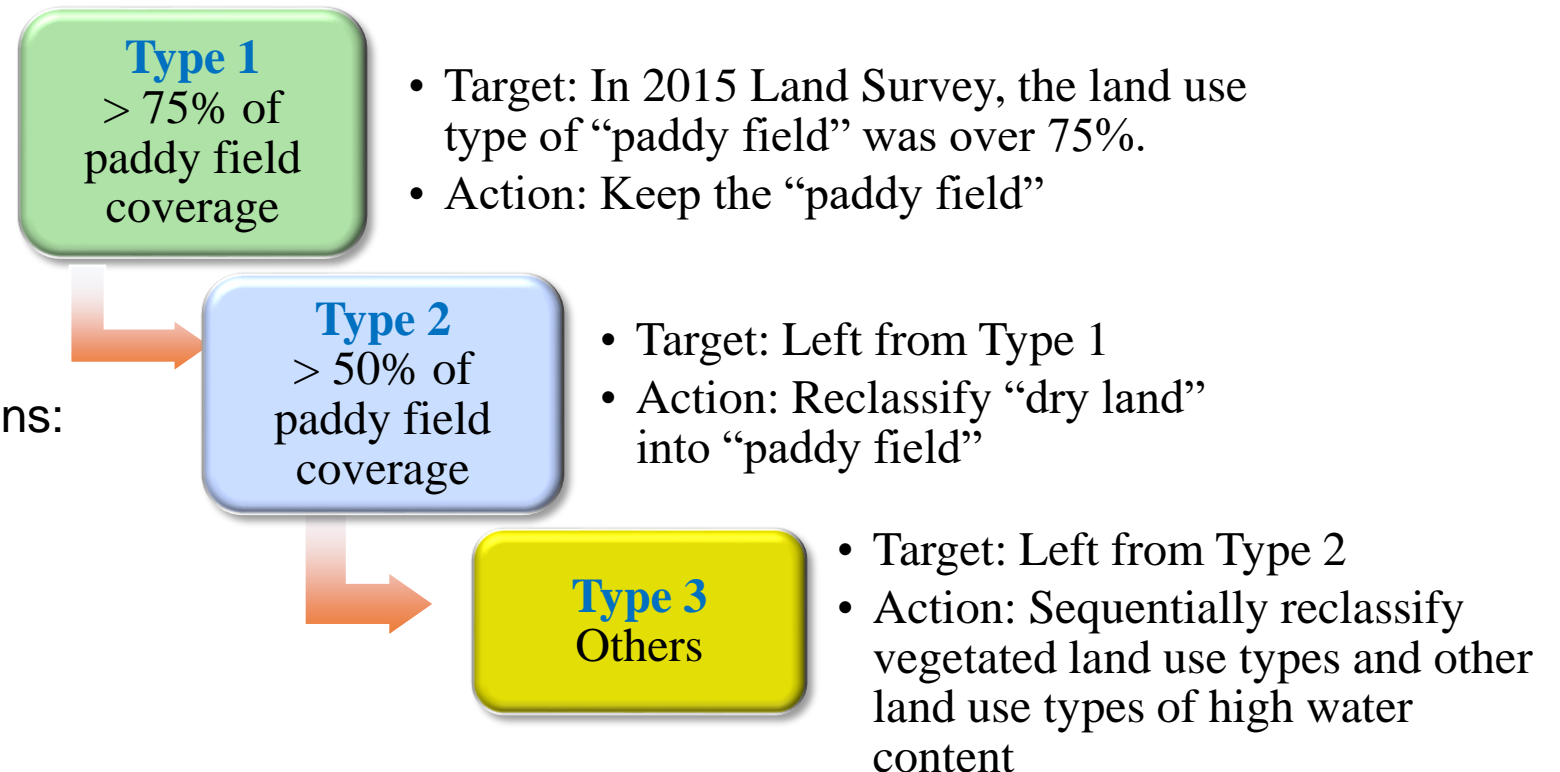

# Methodology (4/8)

## • Reclassification of Paddy field

Distribution of Workstations

Data source	Year of the Data
Construction and Planning Agency, Ministry of the Interior	Digital map, the 2nd Land Survey in 2015
Taoyuan and Shimen Management Offices	Statistical data, planned paddy irrigation area in 2020

# Methodology (5/8)

- Workstations and Groups

Dachu Workstation  
16 Groups

Taoyuan Workstation  
28 Groups

Bade Workstation  
22 Groups  
Chungli Workstation  
2 Groups

# Methodology (7/8)

- Scenarios 1: Plowsole depths

## Scenario 1A

The depth of the soil  
as the depth of  
plowsole

The depths of the soil layers

- Alluvial soil: 20 mm
- Yellow soil: 30 mm
- Other soil layers: 120 mm

## Scenario 1B

Fixed depth at  
6000mm  
as the depth of  
plowsole

as the default values for  
plowsole of HRU paddy  
fields

Set HRU36 ([alluvial soil](#))  
as an example, test the  
following simulations:

- Analyze its hydrological characteristics
- Compare the hydrological change in water quantity

Select appropriate plowsole  
depths for further calibration  
and validation.

# Methodology (6/8)

- Estimation of Streamflow

Observed hydrological data	Year
Water level	2001 ~ 2013
Streamflow	1982 ~ 2002

# Methodology (8/8)

- Model Calibration and Validation

SUFI-2

- 500 simulations
- P-value < 0.05 was regarded as an adjustable sensitivity parameter.

## Evaluation of model simulation results

Statistical value Performance of model simulation	NSE	PBIAS (%) Streamflow	RSR
<b>Very good</b>	$0.75 < \text{NSE} \leq 1.00$	$ \text{PBIAS}  < 10$	$0.00 \leq \text{RSR} \leq 0.50$
<b>Good</b>	$0.65 < \text{NSE} \leq 0.75$	$10 \leq  \text{PBIAS}  < 15$	$0.50 < \text{RSR} \leq 0.60$
<b>Satisfactory</b>	$0.50 < \text{NSE} \leq 0.65$	$15 \leq  \text{PBIAS}  < 25$	$0.60 < \text{RSR} \leq 0.70$
<b>Unsatisfactory</b>	$\text{NSE} \leq 0.50$	$ \text{PBIAS}  \geq 25$	$\text{RSR} > 0.70$

The calibrated SWAT model with **scheduled irrigation** was further applied to simulate the auto-irrigation.

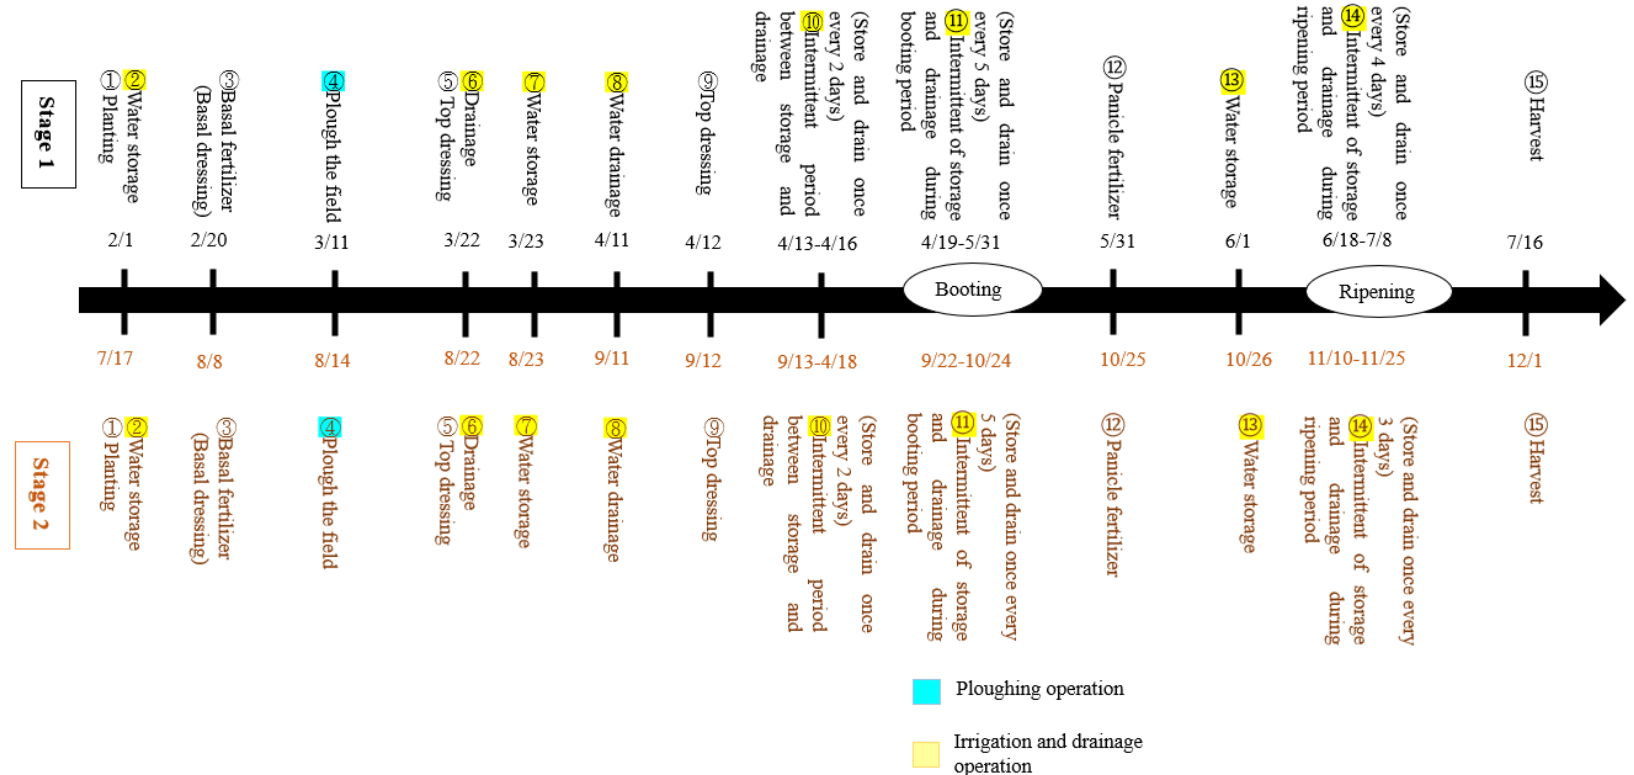

# Methodology (2/8)

## • Scenario 2: Irrigation operations

### Scenario 2A:

**Auto-irrigation** is the system mode to determine the water demand of crops and automatically supply the amount of proper irrigation, in which a threshold of severe water shortage is set by user (AUTO\_WSTR) as the trigger criteria for irrigation. When the system detects that the soil water content (SW) < field water content (FC) in HRU, the AUTO\_WSTR is triggered and the irrigation process starts until the field is saturated with proper water content (Neitsch et al., 2011).

### Scenario 2B: Traditional (Scheduled) irrigation

# Methodology (3/8)

- Traditional (Scheduled) Irrigation

The average water quantity (m<sup>3</sup>/s) of scheduled irrigation provided by the Irrigation Agency were used to calculate the amount of irrigation per unit area (mm/day).

$$\begin{aligned} &\text{Fixed irrigation per unit area} \left( \frac{\text{mm}}{\text{day}} \right) \\ &= \frac{\text{Average of scheduled irrigation} \left( \frac{\text{m}^3}{\text{s}} \right) * 86400}{\text{Irrigation area (ha)} * 10} \end{aligned}$$

Group’s irrigation area (ha)	Fixed irrigation per unit area (mm/day)
Range: 0.27-170.28 ha Average: 63.29 ha	Range: 5.51-19.55 mm/day Average: 9.59 mm/day

# Results and Discussion (1/12)

- Reclassify of paddy fields

# Results and Discussion (2/12)

## Scenario 1

The soil depth as the  
plowsole depth

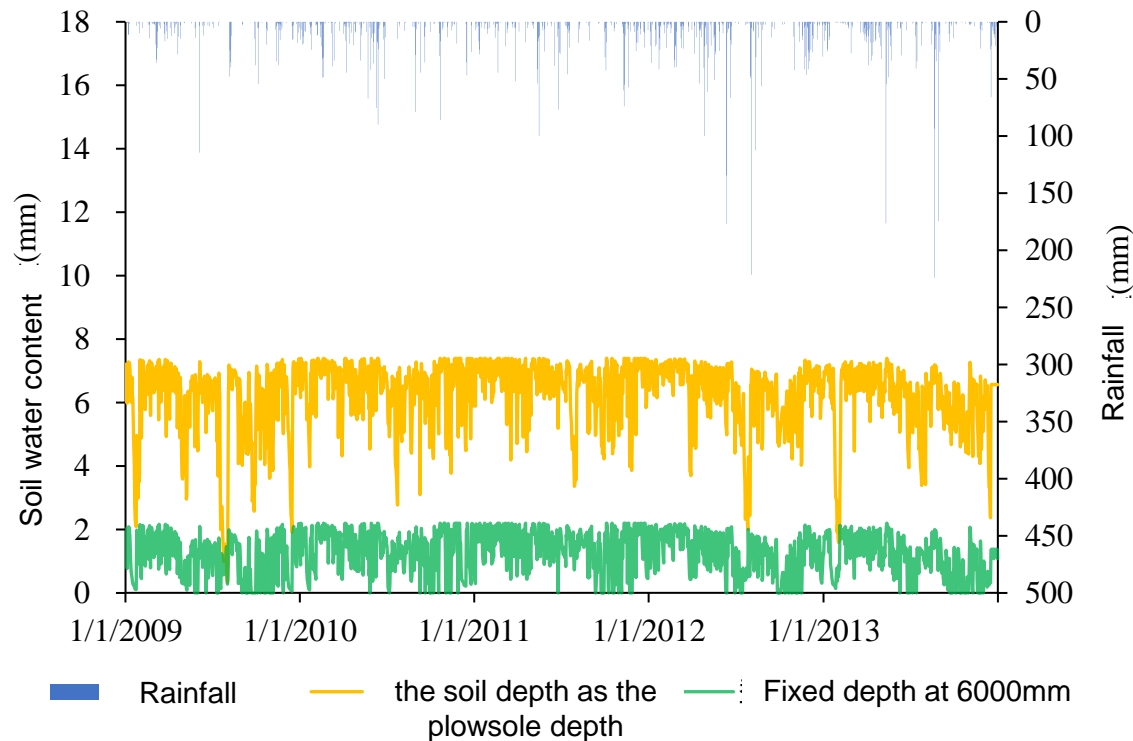

vs.

Fixed depth at 6000mm  
as the plowsole depth

# Results and Discussion (3/12)

- Comparison of plowsole depths: soil water content, infiltration, storage in paddy, and drainage from paddy

Soil water content ( $\text{m}^3$ )

Infiltration ( $\text{m}^3$ )

# Results and Discussion (4/12)

- Comparison of plowsole depths: soil water content, infiltration, storage in paddy, and drainage from paddy

Storage in paddy fields ( $\text{m}^3$ )

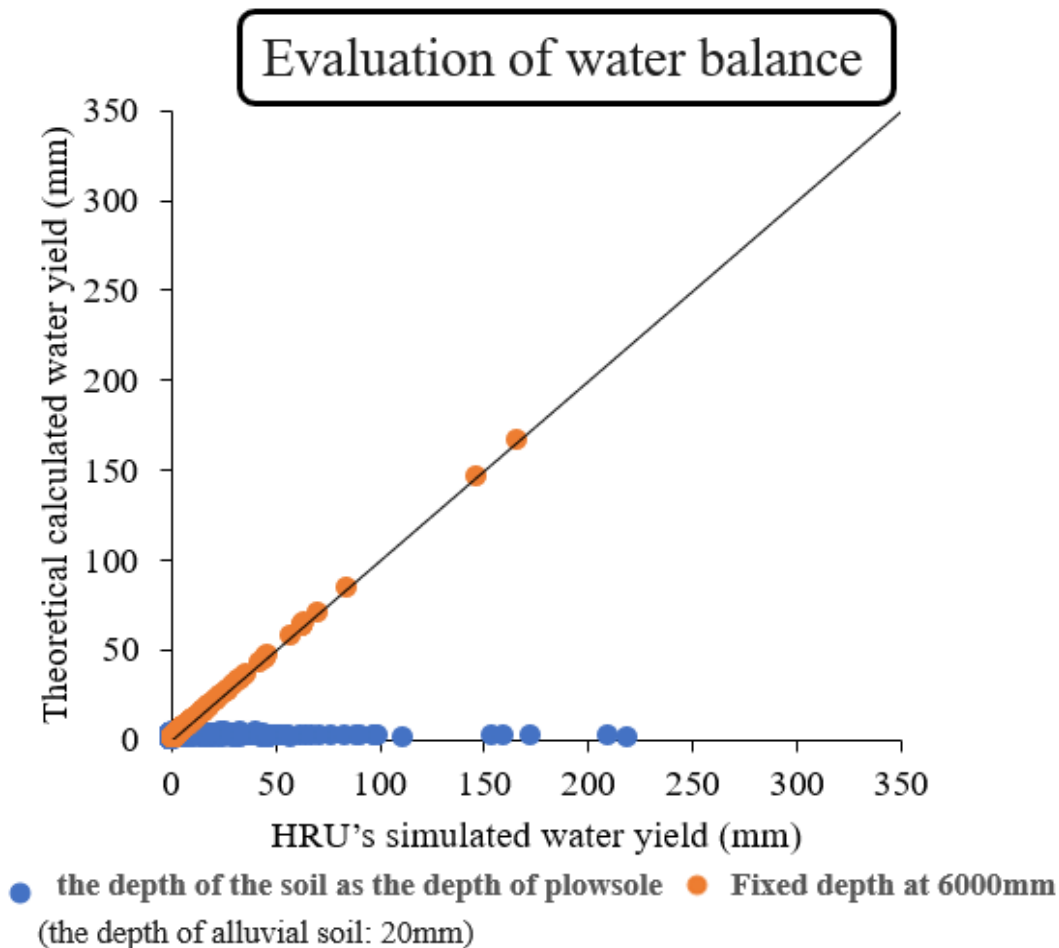

Drainage from paddy ( $\text{m}^3$ )

# Results and Discussion (5/12)

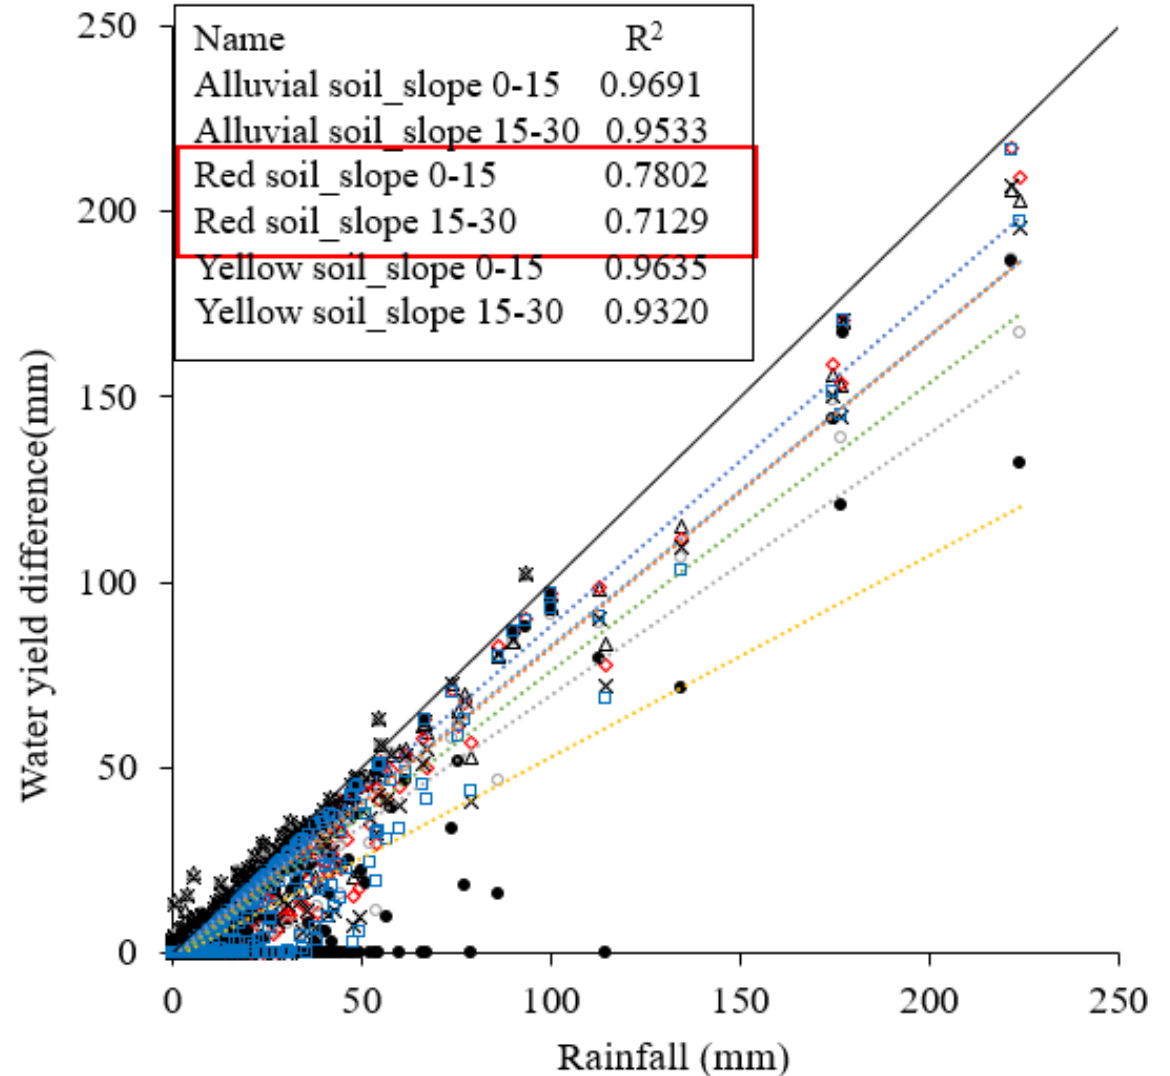

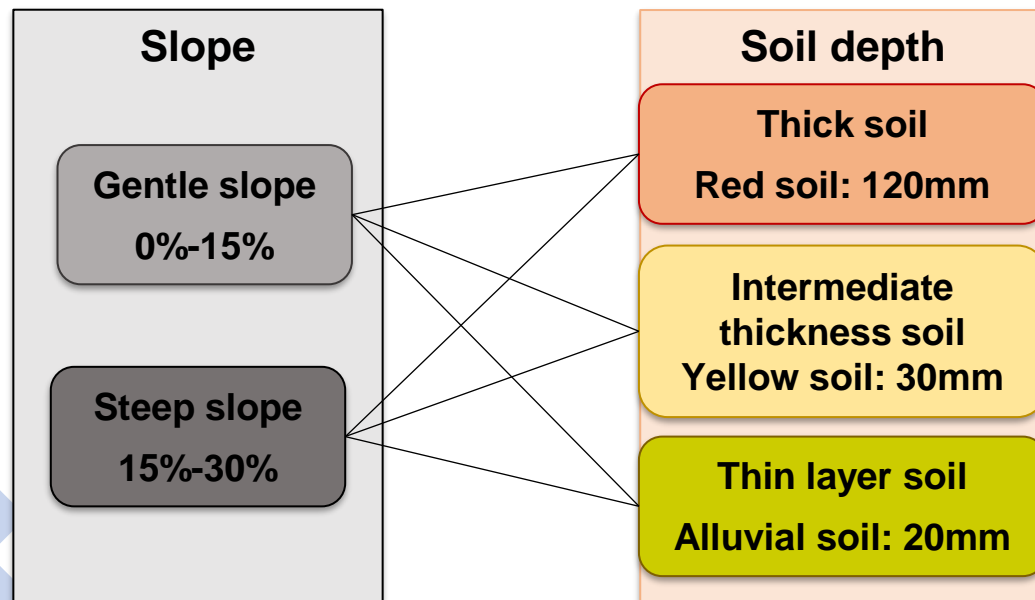

- Analysis of Water Yield at HRUs
  - Verification of simulated and theoretical water yields

# Results and Discussion (6/12)

- Analysis of Water Yield at HRUs
  - Impacts of slope and soil depths

Combinations of Slope and Soil depths (as plowsole depths)

△ Alluvial soil\_slope 0-15    ◇ Alluvial soil\_slope 15-30    ○ Red soil\_slope 0-15  
 • Red soil\_slope 15-30    × Yellow soil\_slope 0-15    □ Yellow soil\_slope 15-30

# Results and Discussion (7/12)

## Scenario 2

Traditional Irrigation

VS.

Auto-Irrigation

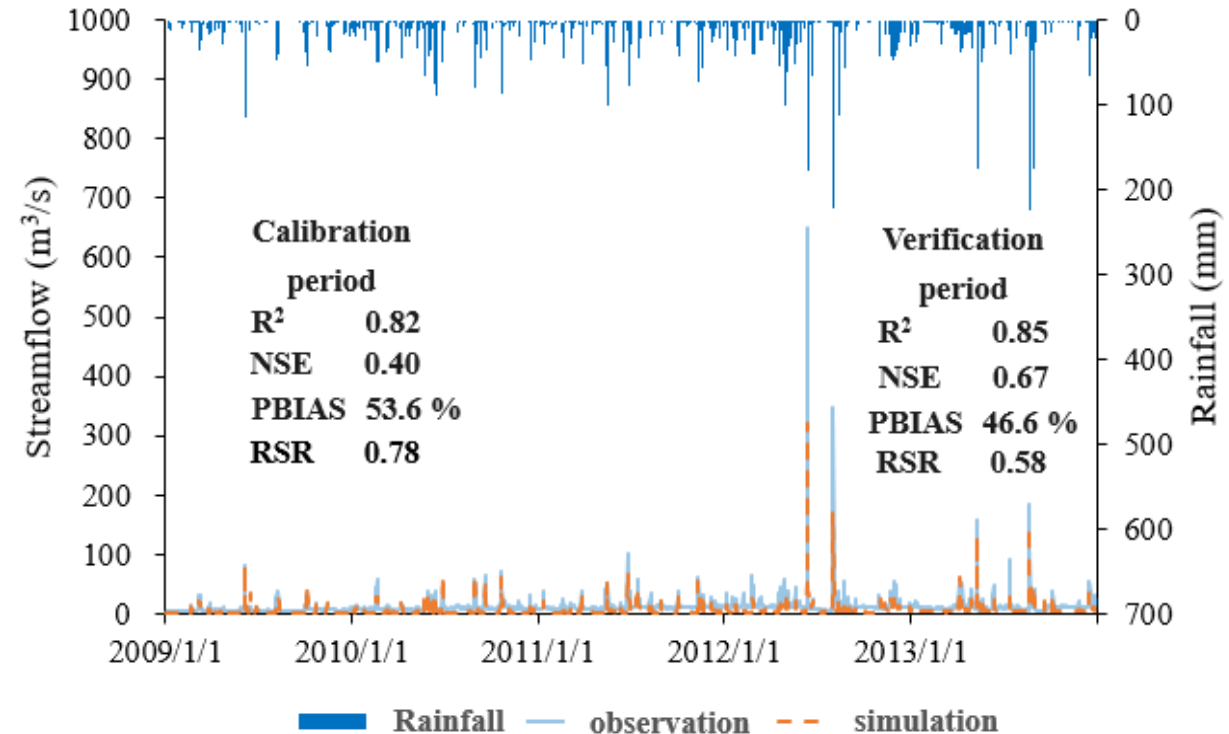

# Results and Discussion (8/12)

- Model Calibration and Validation
  - Traditional irrigation vs. Auto-irrigation

## Traditional Irrigation

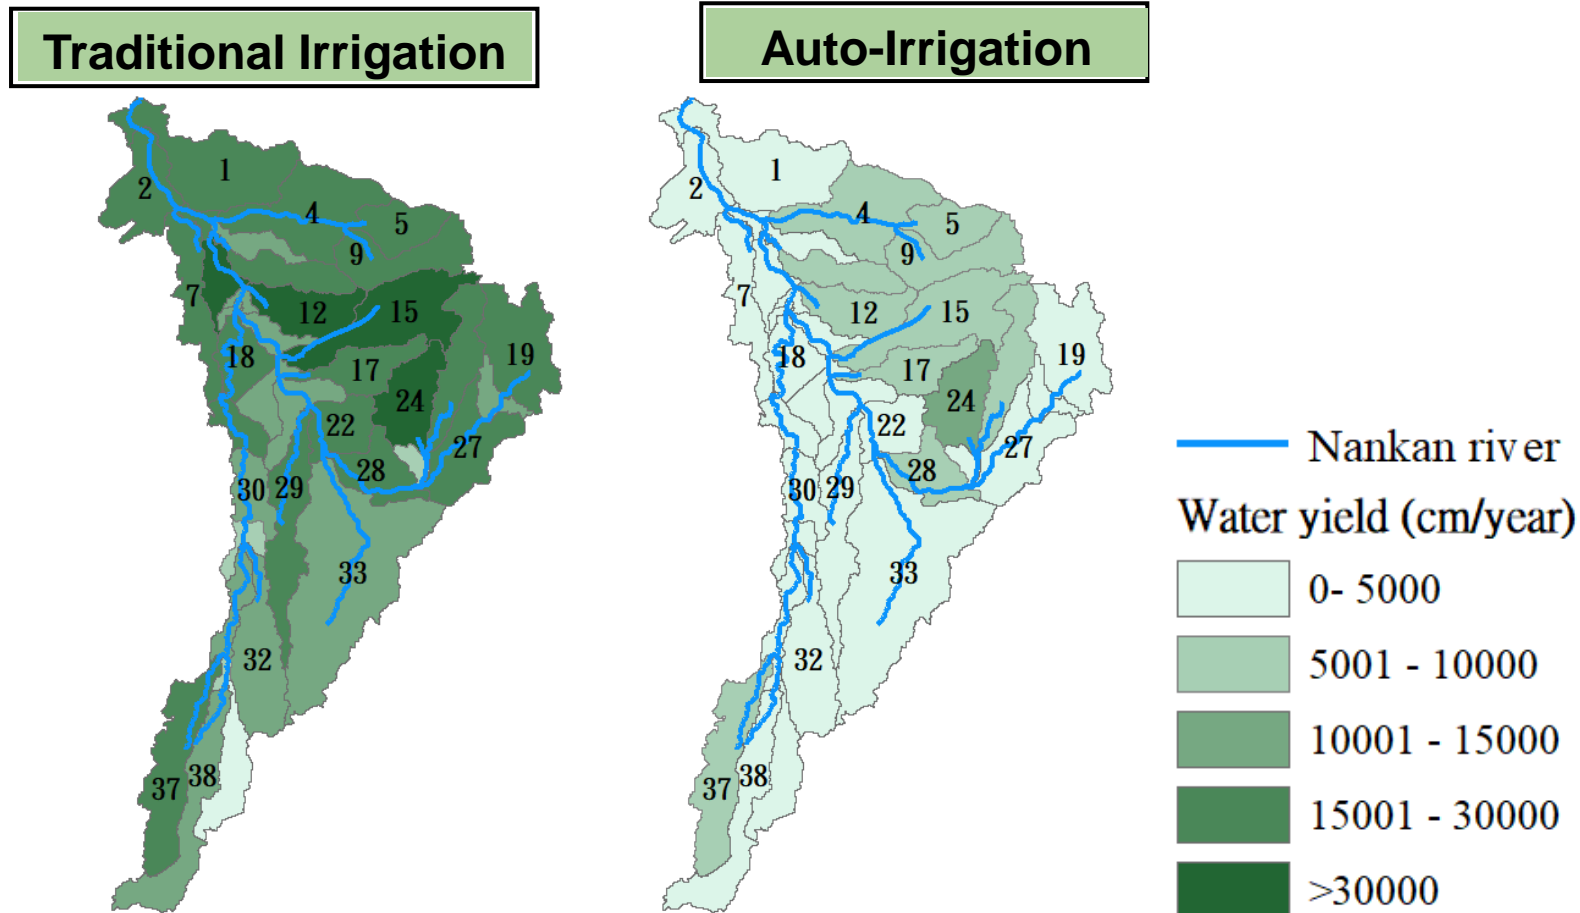

## Auto-Irrigation

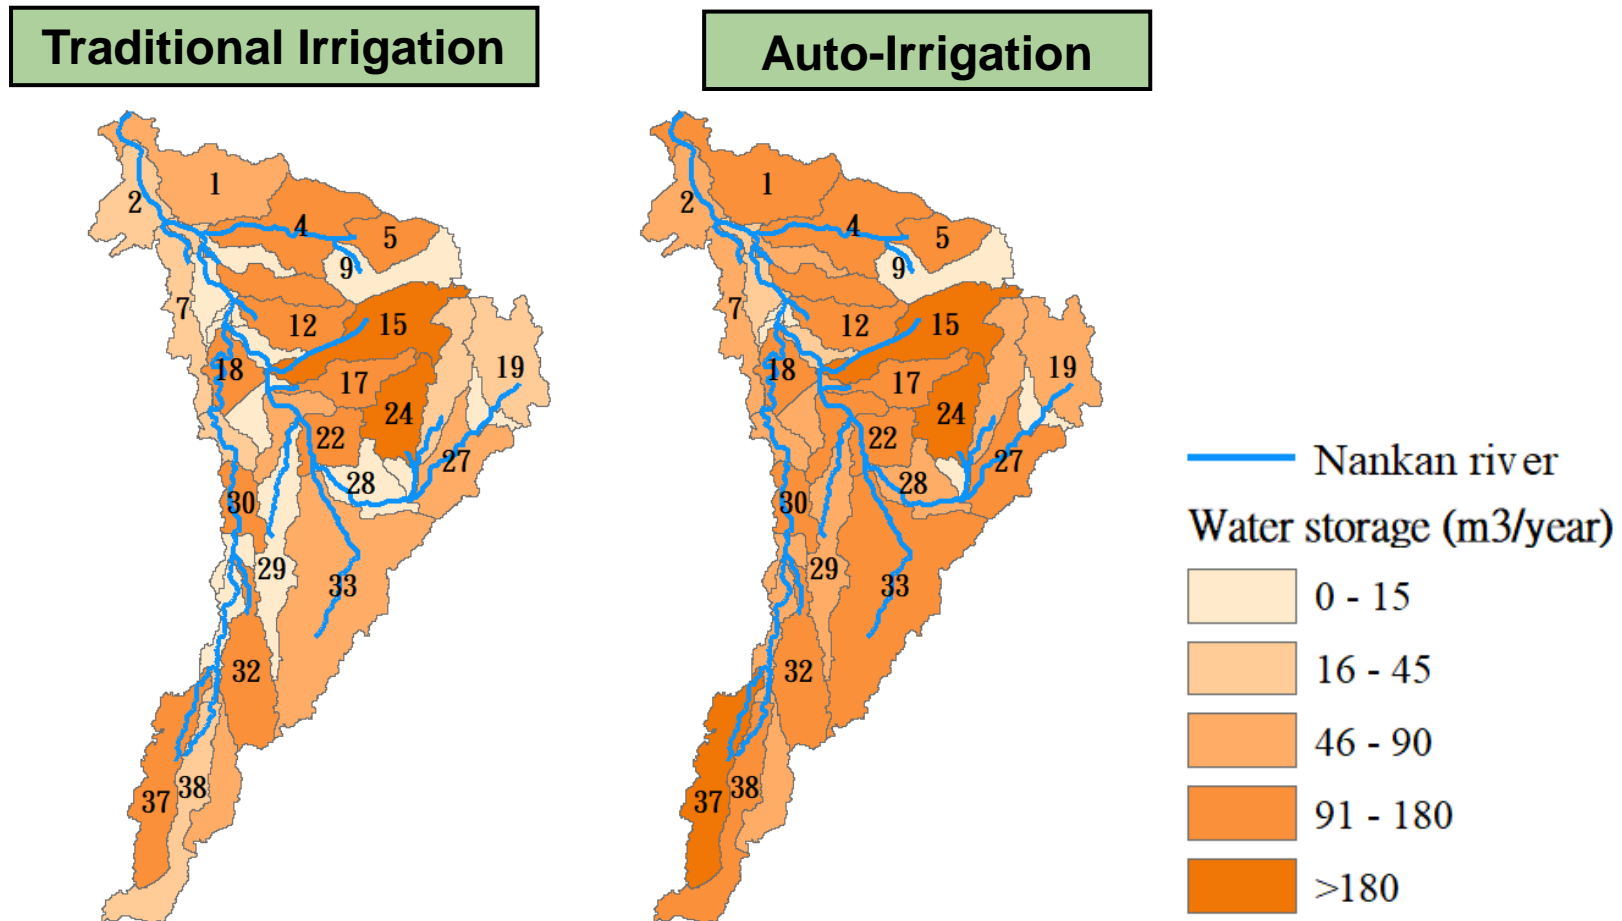

# Results and Discussion (9/12)

- Traditional irrigation vs. Auto-irrigation
  - Annual average **water yield of paddy** HRU at subbasins

# Results and Discussion (10/12)

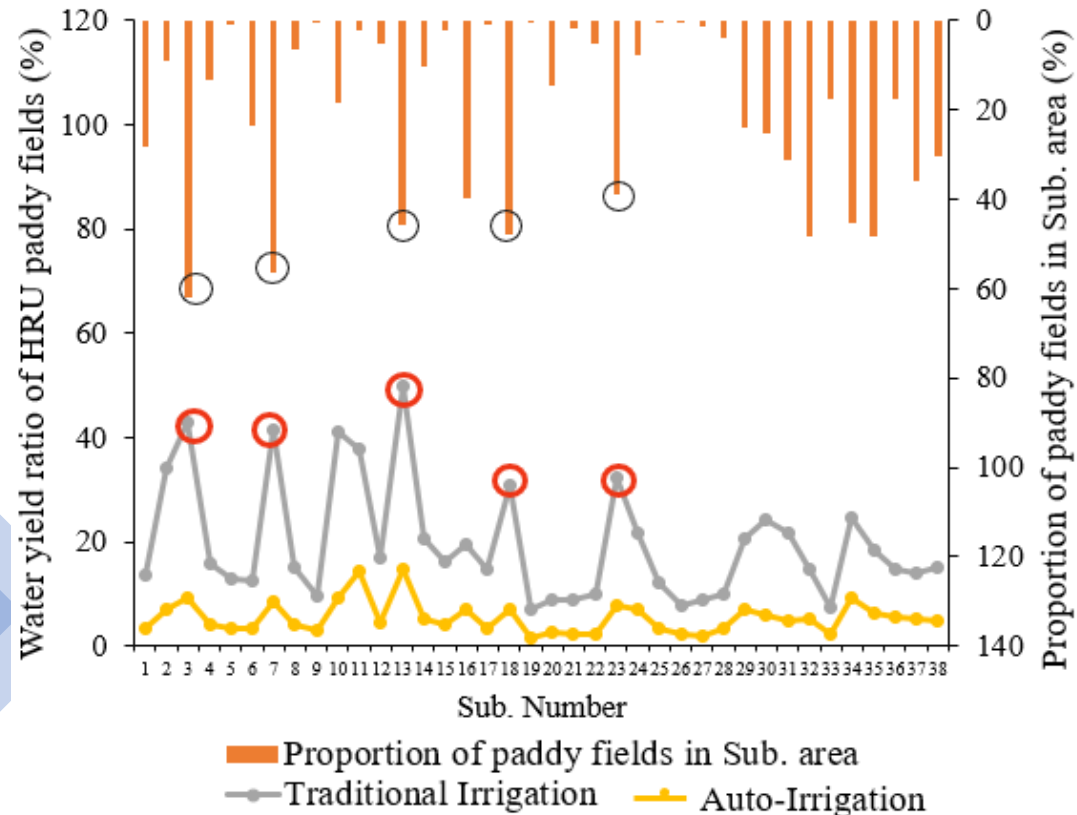

- Traditional irrigation vs. Auto-irrigation
  - Annual average [water storage of paddy](#) at subbasins

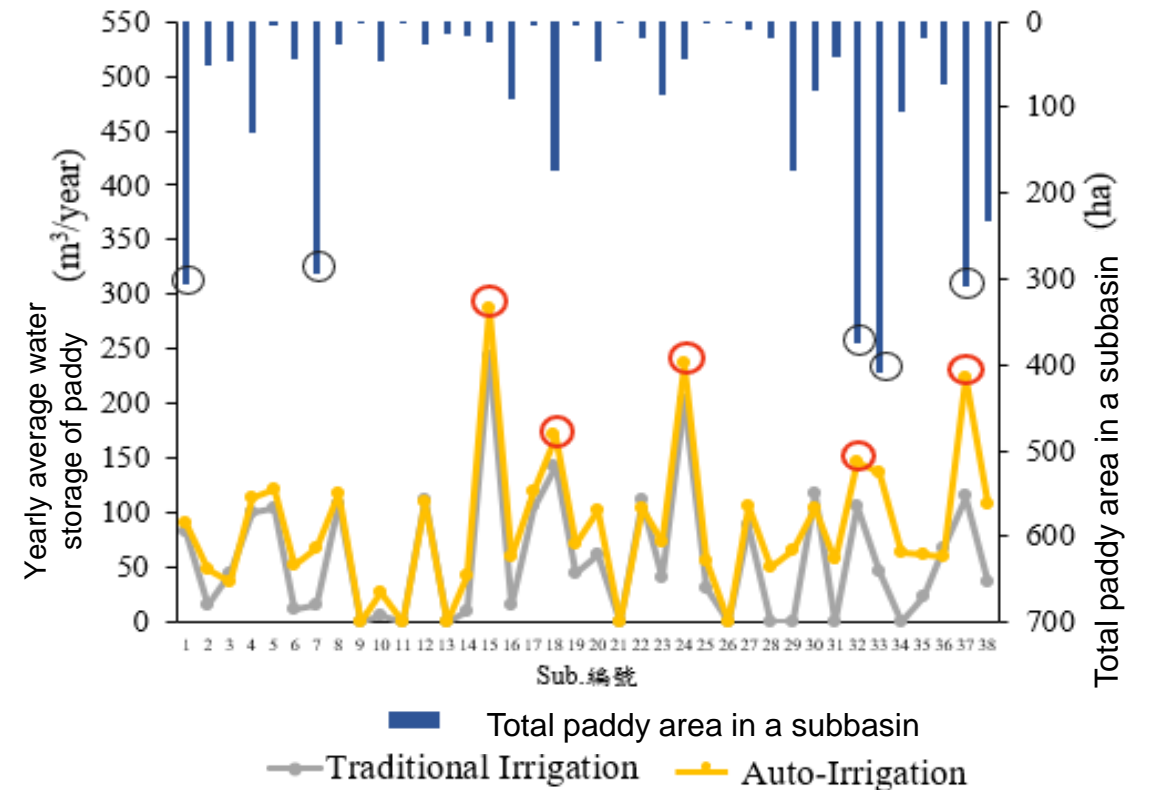

# Results and Discussion (11/12)

- Traditional irrigation vs. Auto-irrigation
  - Paddy HRU contribution to total water yield of a subbasin vs. Area percentage of paddy in a subbasin
  - Yearly average water storage of paddy vs. Total paddy area in a subbasin

HRU Water Yield

Water storage of paddy

# Results and Discussion (12/12)

- Traditional irrigation vs. Auto-irrigation
  - Daily average **water yield of paddy HRU** and **water storage of paddy**

Daily average <b>water yield of paddy HRU</b> (mm/day)			Insight
Irrigation operations	Range (2009-2013)	Average (2009-2013)	
Traditional Irrigation	1902.5 - 2200.7	2038.0	
Auto-irrigation	318.9 - 624.5	480.4	
Daily average <b>water storage of paddy</b> (m <sup>3</sup> /day)			
Irrigation operations	Range (2009-2013)	Average (2009-2013)	
Traditional Irrigation	4.24 - 7.29	6.08	
Auto-irrigation	3.17 - 12.26	9.01	

# Conclusion

- Integration and proper classification of land use could **effectively improve the irrigation coverage of paddy fields** (by an average of 25%), reaching a **total coverage of approximately 70%**, and  $R^2$  value of paddy field coverage increased from 0.52 to 0.82.
- By setting the soil depth as the plowsole depth, **all hydrological characteristics of paddy fields** were **clearly presented**, while **soil infiltration would be enhanced** when setting the plowsole with a fixed depth of 6000mm.
- Under the condition of shallow soil depth and slow slope, the difference between simulated and theoretical water yields is closely correlated with rainfall.
- Auto-irrigation operation is suggested for storing more water in paddy fields and resulting less return water out of paddy fields.

**Thank you for your listening.**
